Box and Jenkins methodology

1. stationarity (if needed),
2. order selection,
3. estimation,
4. diagnostic checking,
5. final order selection,
6. forecasting,
7. ex post analysis.

Methods

- ▶ trend-seasonality decomposition,
- ▶ differencing transformations,
- ▶ Box-Cox transformation.

Differencing transformations

The two most common cases :

- ▶ Time series with a d -degree polynomial : ∇^d .
- ▶ Time series with a s -period seasonality : ∇_s^D .

Box-Cox transformation

In order to remove a “variance problem”, the Box-Cox transformation is sometimes used :

$$\frac{X_t^\lambda - 1}{\lambda}$$

with $\lambda \in \mathbb{R}$.

Note that :

$$\frac{X_t^\lambda - 1}{\lambda} \xrightarrow{\lambda \rightarrow 0} \ln(X_t).$$

Remark

One can find some stationarity tests that aren't comprehensive.

Ex post analysis

In practice

- ▶ A very slowly decrease of the time series “ACF” suggests differencing at lag 1.
- ▶ A very slowly decrease of the time series “ACF” every s multiple lags suggests differencing at lag s .

Differencing is iteratively done, and generally : $d \leq 2$ and $D \leq 2$.

We consider now that the transformed (or not) time series can potentially be fitted by a zero-mean ARMA model.

To select the model order, one can use :

- ▶ confidence intervals,
- ▶ corner method,
- ▶ information criterium,
- ▶ heuristic.

Use of confidence intervals

Idea : empirically establish maximum values for p and q .

- ▶ For a AR (p) process :

$$\forall h > p : \sqrt{n}\hat{r}(h) \xrightarrow{\mathcal{L}} \mathcal{N}(0, 1).$$

One can define a confidence interval of level 95% and search the number of lags for which 95% of the $\hat{r}(h)$

are in $\left[-\frac{1.96}{\sqrt{n}}, \frac{1.96}{\sqrt{n}}\right]$.

- ▶ For a MA (q) process :

$$\forall h > q : \sqrt{n}\hat{\rho}(h) \xrightarrow{\mathcal{L}} \mathcal{N}\left(0, 1 + 2 \sum_{k=1}^q \rho^2(k)\right).$$

One can define a confidence interval of level 95% and search the number of lags for which 95% of the $\hat{\rho}(h)$ are in :

$$\left[-\frac{1.96}{\sqrt{n}} \left(1 + 2 \sum_{k=1}^q \hat{\rho}^2(k)\right)^{\frac{1}{2}}, \frac{1.96}{\sqrt{n}} \left(1 + 2 \sum_{k=1}^q \hat{\rho}^2(k)\right)^{\frac{1}{2}}\right].$$

Information criterium

Aim : search a model for which a chosen information criterium is minimal.

Ex post analysis

Heuristic

In order to draw hypothesis, find “significant” autocorrelations :

- ▶ For the AR part : partial autocorrelations.
- ▶ For the MA part : (simple) autocorrelations.

Significance test of the parameters

For example, we consider the following test for φ_p :

$$\begin{cases} H_0 : \text{le processus est un ARMA}(p-1, q) (\varphi_p = 0) \\ H_1 : \text{le processus est un ARMA}(p, q) (\varphi_p \neq 0) \end{cases}$$

We use the student statistic :

$$t = \frac{|\hat{\varphi}_p|}{\sqrt{\widehat{\text{Var}}(\hat{\varphi}_p)}}.$$

We reject H_0 at the 5% level if $|t| > 1.96$.

selection

Forecasting

Ex post analysis

Whiteness and normality of the residuals

- ▶ Whiteness : Ljung–Box test.
- ▶ Normality : Shapiro–Wilk.

Note that if the normality of the residuals is rejected, it could be useful to add an ARCH or GARCH part. . .

Final order selection

There are two main ways to finally select a model :

- ▶ Information criterium (e.g. AIC or BIC)).
- ▶ Predictive power.

Ex post analysis

Idea : truncate the time series and measure the forecasting error with an indicator such as the Root Mean Square Error (RMSE) or the Mean Average Percentage Error (MAPE) :

$$\text{RMSE} = \sqrt{\frac{1}{T} \sum_{t=1}^T (x_t - \hat{x}_t)^2},$$

$$\text{MAPE} = \frac{1}{T} \sum_{t=1}^T \left| \frac{x_t - \hat{x}_t}{x_t} \right|.$$
